# COMP9417 Machine Learning and Data Mining Final Examination: SAMPLE QUESTIONS

HERE ARE SEVEN QUESTIONS WHICH ARE REPRESENTATIVE OF THE TYPE THAT WILL BE IN THE FINAL EXAM. EACH QUESTION IS OF EQUAL VALUE. THERE WILL BE SOME DEGREE OF CHOICE AS TO WHICH QUESTIONS YOU CAN ANSWER. CANDIDATES MAY BRING AUTHORISED CALCULATORS TO THE EXAMINATION, BUT NO OTHER MATERIALS WILL BE PERMITTED.

# Question 1 [20 marks]

Association Rule Learning & and ILP

# A) [7 marks]

An association rule has the form  $A \to C$  where A is the antecedent and C is the consequent. Suppose you have a database of one million transactions.

- 1) If an association rule has 90% support, how many transactions contain all the items in A?
- 2) For the same rule, how many transactions contain all the items in C?
- 3) For the same rule, how many transactions contain all the items in both A and C?
- 4) If another rule has 40% support and 100% confidence, how many transactions contain all the items in A?
- 5) If yet another rule has 40% support and 50% confidence, how many transactions contain all the items in A?

# B) [3 marks]

You are mining a data warehouse. In three sentences or less propose a method to derive all candidate item sets of size k + 1 from the k-item sets with at least minimum support.

# (C) [4 marks]

Consider the following two clauses:

$$C = P(A, x) \vee Q(A, B)$$
 and  $C_1 = Q(y, B) \vee T(y)$ 

Using inverse resolution, provide at least one solution for  $C_2$ . [Show all substitutions].

# D [6 marks]

Consider the following two clauses:

$$C = Q(A, x, B) \vee S(y, B)$$
 and  $C_1 = S(w, B) \vee \neg R(z)$ 

Using inverse resolution, provide at least two solutions for  $C_2$ . [Show all substitutions].

# Question 2 [20 marks]

Comparing Lazy and Eager Learning

The following truth table gives an "m-of-n function" for three Boolean variables, where "1" denotes true and "0" denotes false. In this case the target function is: "exactly two out of three variables are true".

X	Y	Z	Class
0	0	0	false
0	0	1	false
0	1	0	false
0	1	1	true
1	0	0	false
1	0	1	true
1	1	0	true
1	1	1	false

# A) [4 marks]

Construct a decision tree which is complete and correct for the examples in the table. [Hint: draw a diagram.]

# B) [4 marks]

Construct a set of **ordered** classification rules which is complete and correct for the examples in the table. [Hint: use an *if-then-else* representation.]

# C) [10 marks]

Suppose we define a simple measure of distance between two equal length strings of Boolean values, as follows. The distance between two such strings  $B_1$  and  $B_2$  is:

$$\operatorname{distance}(B_1,B_2) = |(\sum B_1) - (\sum B_2)|$$

where  $\sum B_i$  is simply the number of variables with value 1 in string  $B_i$ . For example:

$$distance(\langle 0,0,0\rangle,\langle 1,1,1\rangle)=|0-3|=3$$

and

distance(
$$(1, 0, 0), (0, 1, 0)$$
) =  $|1 - 1| = 0$ 

What is the LOOCV ("Leave—one—out cross-validation") error of 2—Nearest Neighbour using our distance function on the examples in the table? [Show your working.]

# D) [2 marks]

Compare your three models. Which do you conclude provides a better representation for this particular problem? Give your reasoning (one sentence).

# Question 3 [20 Marks]

Mistake Bounds

Consider the following learning problem in which each instance is an integer in the range [1,5], and in which each hypothesis is an interval over the integers. More precisely, each hypothesis h in the hypothesis space H is an interval of the form  $a \le x \le b$ , where a and b are integer constants and x refers to the instance. For example, the hypothesis  $3 \le x \le 5$  classifies the integers 3, 4 and 5 as positive and all others as negative.

Instance	Class
1	Negative
2	Positive
3	Positive
4	Positive
5	Negative

# A) [15 marks]

Apply the Halving Algorithm to the five examples in the order in which they appear in the table above. Show each class prediction and whether or not it is a mistake, plus the initial G and S sets and those at the end of each iteration.

# B) [5 marks]

What is the worst-case mistake bound for the Halving Algorithm given the hypothesis space described above? Give an informal derivation of your bound.

# Question 4 [20 marks]

Unsupervised Learning

# A) [8 marks]

Suggest a top-down algorithm for hierarchical clustering.

# B) [8 marks]

Describe the standard k-means clustering algorithm in terms of learning the edges in a bipartite graph having k cluster vertices and N instance vertices.

# (C) [4 marks]

Explain the category utility measure used in the COBWEB conceptual clustering algorithm in terms of Bayesian learning.

# Question 5 [20 Marks]

Computational Learning Theory

#### A) [8 marks]

An instance space X is defined using m Boolean attributes. Let the hypothesis space H be the set of decision trees defined on X (you can assume two classes). What is the largest set of instances in this setting which is shattered by H? [Show your reasoning.]

# B) [10 marks]

Suppose we have a consistent learner with a hypothesis space restricted to conjunctions of exactly 8 attributes, each with values {true, false, don't care}. What is the size of this learner's hypothesis space? Give the formula for the number of examples sufficient to learn with probability at least 95% an approximation of any hypothesis in this space with error of at most 10%. [Note: you are *not* required to compute the solution.]

#### (C) [2 marks]

Informally, which of the following are consequences of the No Free Lunch theorem:

- a) averaged over all possible training sets, the variance of a learning algorithm dominates its bias
- b) averaged over all possible training sets, no learning algorithm has a better off-training set error than any other
- c) averaged over all possible target concepts, the bias of a learning algorithm dominates its variance
- d) averaged over all possible target concepts, no learning algorithm has a better offtraining set error than any other
- e) averaged over all possible target concepts and training sets, no learning algorithm is independent of the choice of representation in terms of its classification error

# Question 6 [20 marks]

Ensemble Learning

# A) [8 marks]

As model complexity increases from low to high, what effect does this have on:

- 1) Bias?
- 2) Variance?
- 3) Predictive accuracy on training data?
- 4) Predictive accuracy on test data?

#### B) [3 marks]

Is decision tree learning relatively stable? Describe decision tree learning in terms of bias and variance in no more than two sentences.

# (C) [3 marks]

Is nearest neighbour relatively stable? Describe nearest neighbour in terms of bias and variance in no more than two sentences.

# D) [3 marks]

Bagging reduces bias. True or false? Give a one sentence explanation of your answer.

#### E) [3 marks]

Bagging reduces variance. True or false? Give a one sentence explanation of your answer.

# Question 7 [20 marks]

Bayesian Learning

# A) [4 marks]

Explain the difference between the maximum a posteriori hypothesis  $H_{\mathrm{MAP}}$  and the maximum likelihood hypothesis  $H_{\mathrm{ML}}$ .

#### B) [2 marks]

Consider a two-class learning problem to "Play tennis", with two Boolean attributes, "Cloudy" and "Windy". Draw the Bayesian network corresponding to a Naive Bayes classifier for this problem.

# (C) [10 marks]

Given the following examples, calculate *all* the probabilities required for your Naive Bayes classifier to be able to decide whether to play or not:

Instance No.	Cloudy	Windy	Play tennis
1	0	0	no
2	0	1	no
3	1	1	no
4	0	0	no
5	0	1	yes
6	1	0	yes

#### D) [4 marks]

To which class would your Naive Bayes classifier assign each of the following instances?

Instance No.	Cloudy	Windy	Play tennis
7	0	0	?
8	0	1	?

Name of Candidate:	
Student number:	
Signature:	

# COMP9417 Machine Learning and Data Mining Final Examination: SAMPLE QUESTIONS

HERE ARE SEVEN QUESTIONS WHICH ARE REPRESENTATIVE OF THE TYPE THAT WILL BE IN THE FINAL EXAM. EACH QUESTION IS OF EQUAL VALUE. THERE WILL BE SOME DEGREE OF CHOICE AS TO WHICH QUESTIONS YOU CAN ANSWER. CANDIDATES MAY BRING AUTHORISED CALCULATORS TO THE EXAMINATION, BUT NO OTHER MATERIALS WILL BE PERMITTED.

# Question 1 [20 marks]

Association Rule Learning & and ILP

# A) [7 marks]

An association rule has the form  $A \to C$  where A is the antecedent and C is the consequent. Suppose you have a database of one million transactions.

- 1) If an association rule has 90% support, how many transactions contain all the items in A?
- 2) For the same rule, how many transactions contain all the items in C?
- 3) For the same rule, how many transactions contain all the items in both A and C?
- 4) If another rule has 40% support and 100% confidence, how many transactions contain all the items in A?
- 5) If yet another rule has 40% support and 50% confidence, how many transactions contain all the items in A?

# B) [3 marks]

You are mining a data warehouse. In three sentences or less propose a method to derive all candidate item sets of size k + 1 from the k-item sets with at least minimum support.

# (C) [4 marks]

Consider the following two clauses:

$$C = P(A, x) \vee Q(A, B)$$
 and  $C_1 = Q(y, B) \vee T(y)$ 

Using inverse resolution, provide at least one solution for  $C_2$ . [Show all substitutions].

# D [6 marks]

Consider the following two clauses:

$$C = Q(A, x, B) \vee S(y, B)$$
 and  $C_1 = S(w, B) \vee \neg R(z)$ 

Using inverse resolution, provide at least two solutions for  $C_2$ . [Show all substitutions].

# Question 2 [20 marks]

Comparing Lazy and Eager Learning

The following truth table gives an "m-of-n function" for three Boolean variables, where "1" denotes true and "0" denotes false. In this case the target function is: "exactly two out of three variables are true".

X	Y	Z	Class
0	0	0	false
0	0	1	false
0	1	0	false
0	1	1	true
1	0	0	false
1	0	1	true
1	1	0	true
1	1	1	false

# A) [4 marks]

Construct a decision tree which is complete and correct for the examples in the table. [Hint: draw a diagram.]

# B) [4 marks]

Construct a set of **ordered** classification rules which is complete and correct for the examples in the table. [Hint: use an *if-then-else* representation.]

# C) [10 marks]

Suppose we define a simple measure of distance between two equal length strings of Boolean values, as follows. The distance between two such strings  $B_1$  and  $B_2$  is:

$$\operatorname{distance}(B_1,B_2) = |(\sum B_1) - (\sum B_2)|$$

where  $\sum B_i$  is simply the number of variables with value 1 in string  $B_i$ . For example:

$$distance(\langle 0,0,0\rangle,\langle 1,1,1\rangle)=|0-3|=3$$

and

distance(
$$(1, 0, 0), (0, 1, 0)$$
) =  $|1 - 1| = 0$ 

What is the LOOCV ("Leave—one—out cross-validation") error of 2—Nearest Neighbour using our distance function on the examples in the table? [Show your working.]

# D) [2 marks]

Compare your three models. Which do you conclude provides a better representation for this particular problem? Give your reasoning (one sentence).

# Question 3 [20 Marks]

Mistake Bounds

Consider the following learning problem in which each instance is an integer in the range [1,5], and in which each hypothesis is an interval over the integers. More precisely, each hypothesis h in the hypothesis space H is an interval of the form  $a \le x \le b$ , where a and b are integer constants and x refers to the instance. For example, the hypothesis  $3 \le x \le 5$  classifies the integers 3, 4 and 5 as positive and all others as negative.

Instance	Class
1	Negative
2	Positive
3	Positive
4	Positive
5	Negative

# A) [15 marks]

Apply the Halving Algorithm to the five examples in the order in which they appear in the table above. Show each class prediction and whether or not it is a mistake, plus the initial G and S sets and those at the end of each iteration.

# B) [5 marks]

What is the worst-case mistake bound for the Halving Algorithm given the hypothesis space described above? Give an informal derivation of your bound.

# Question 4 [20 marks]

Unsupervised Learning

# A) [8 marks]

Suggest a top-down algorithm for hierarchical clustering.

# B) [8 marks]

Describe the standard k-means clustering algorithm in terms of learning the edges in a bipartite graph having k cluster vertices and N instance vertices.

# (C) [4 marks]

Explain the category utility measure used in the COBWEB conceptual clustering algorithm in terms of Bayesian learning.

# Question 5 [20 Marks]

Computational Learning Theory

#### A) [8 marks]

An instance space X is defined using m Boolean attributes. Let the hypothesis space H be the set of decision trees defined on X (you can assume two classes). What is the largest set of instances in this setting which is shattered by H? [Show your reasoning.]

# B) [10 marks]

Suppose we have a consistent learner with a hypothesis space restricted to conjunctions of exactly 8 attributes, each with values {true, false, don't care}. What is the size of this learner's hypothesis space? Give the formula for the number of examples sufficient to learn with probability at least 95% an approximation of any hypothesis in this space with error of at most 10%. [Note: you are *not* required to compute the solution.]

#### (C) [2 marks]

Informally, which of the following are consequences of the No Free Lunch theorem:

- a) averaged over all possible training sets, the variance of a learning algorithm dominates its bias
- b) averaged over all possible training sets, no learning algorithm has a better off-training set error than any other
- c) averaged over all possible target concepts, the bias of a learning algorithm dominates its variance
- d) averaged over all possible target concepts, no learning algorithm has a better offtraining set error than any other
- e) averaged over all possible target concepts and training sets, no learning algorithm is independent of the choice of representation in terms of its classification error

# Question 6 [20 marks]

Ensemble Learning

# A) [8 marks]

As model complexity increases from low to high, what effect does this have on:

- 1) Bias?
- 2) Variance?
- 3) Predictive accuracy on training data?
- 4) Predictive accuracy on test data?

#### B) [3 marks]

Is decision tree learning relatively stable? Describe decision tree learning in terms of bias and variance in no more than two sentences.

# (C) [3 marks]

Is nearest neighbour relatively stable? Describe nearest neighbour in terms of bias and variance in no more than two sentences.

# D) [3 marks]

Bagging reduces bias. True or false? Give a one sentence explanation of your answer.

#### E) [3 marks]

Bagging reduces variance. True or false? Give a one sentence explanation of your answer.

# Question 7 [20 marks]

Bayesian Learning

# A) [4 marks]

Explain the difference between the maximum a posteriori hypothesis  $H_{\mathrm{MAP}}$  and the maximum likelihood hypothesis  $H_{\mathrm{ML}}$ .

#### B) [2 marks]

Consider a two-class learning problem to "Play tennis", with two Boolean attributes, "Cloudy" and "Windy". Draw the Bayesian network corresponding to a Naive Bayes classifier for this problem.

# (C) [10 marks]

Given the following examples, calculate *all* the probabilities required for your Naive Bayes classifier to be able to decide whether to play or not:

Instance No.	Cloudy	Windy	Play tennis
1	0	0	no
2	0	1	no
3	1	1	no
4	0	0	no
5	0	1	yes
6	1	0	yes

#### D) [4 marks]

To which class would your Naive Bayes classifier assign each of the following instances?

Instance No.	Cloudy	Windy	Play tennis
7	0	0	?
8	0	1	?

Name of Candidate:	
Student number:	
Signature:	

# COMP9417 Machine Learning and Data Mining Final Examination: SAMPLE QUESTIONS

HERE ARE SEVEN QUESTIONS WHICH ARE REPRESENTATIVE OF THE TYPE THAT WILL BE IN THE FINAL EXAM. EACH QUESTION IS OF EQUAL VALUE, AND SHOULD NOT TAKE LONGER THAN 30 MINUTES TO COMPLETE. IN THE ACTUAL EXAM THERE WILL BE SOME DEGREE OF CHOICE AS TO WHICH QUESTIONS YOU CAN ANSWER. CANDIDATES MAY BRING AUTHORISED CALCULATORS TO THE EXAMINATION, BUT NO OTHER MATERIALS WILL BE PERMITTED.

# Question 1 [20 marks]

Association Rule Learning & and ILP

# A) [7 marks]

An association rule has the form  $A \to C$  where A is the antecedent and C is the consequent. Suppose you have a database of one million transactions.

- 1) If an association rule has 90% support, how many transactions contain all the items in A?
- 2) For the same rule, how many transactions contain all the items in C?
- 3) For the same rule, how many transactions contain all the items in both A and C?
- 4) If another rule has 40% support and 100% confidence, how many transactions contain all the items in A?
- 5) If yet another rule has 40% support and 50% confidence, how many transactions contain all the items in A?

# B) [3 marks]

You are mining a data warehouse. In three sentences or less propose a method to derive all candidate item sets of size k + 1 from the k-item sets with at least minimum support.

# C) [4 marks]

Consider the following two clauses:

$$C = P(A, x) \vee Q(A, B)$$
 and  $C_1 = Q(y, B) \vee T(y)$ 

Using inverse resolution, provide at least one solution for  $C_2$ . [Show all substitutions].

# D [6 marks]

Consider the following two clauses:

$$C = Q(A, x, B) \vee S(y, B)$$
 and  $C_1 = S(w, B) \vee \neg R(z)$ 

Using inverse resolution, provide at least two solutions for  $C_2$ . [Show all substitutions].

# Question 2 [20 marks]

Comparing Lazy and Eager Learning

The following truth table gives an "m-of-n function" for three Boolean variables, where "1" denotes true and "0" denotes false. In this case the target function is: "exactly two out of three variables are true".

X	Y	Z	Class
0	0	0	false
0	0	1	false
0	1	0	false
0	1	1	true
1	0	0	false
1	0	1	true
1	1	0	true
1	1	1	false

# A) [4 marks]

Construct a decision tree which is complete and correct for the examples in the table. [Hint: draw a diagram.]

# B) [4 marks]

Construct a set of **ordered** classification rules which is complete and correct for the examples in the table. [Hint: use an *if-then-else* representation.]

# C) [10 marks]

Suppose we define a simple measure of distance between two equal length strings of Boolean values, as follows. The distance between two such strings  $B_1$  and  $B_2$  is:

$$\operatorname{distance}(B_1,B_2) = |(\sum B_1) - (\sum B_2)|$$

where  $\sum B_i$  is simply the number of variables with value 1 in string  $B_i$ . For example:

$$distance(\langle 0,0,0\rangle,\langle 1,1,1\rangle)=|0-3|=3$$

and

distance(
$$(1, 0, 0), (0, 1, 0)$$
) =  $|1 - 1| = 0$ 

What is the LOOCV ("Leave—one—out cross-validation") error of 2—Nearest Neighbour using our distance function on the examples in the table? [Show your working.]

# D) [2 marks]

Compare your three models. Which do you conclude provides a better representation for this particular problem? Give your reasoning (one sentence).

# Question 3 [20 Marks]

Mistake Bounds

Consider the following learning problem in which each instance is an integer in the range [1,5], and in which each hypothesis is an interval over the integers. More precisely, each hypothesis h in the hypothesis space H is an interval of the form  $a \le x \le b$ , where a and b are integer constants and x refers to the instance. For example, the hypothesis  $3 \le x \le 5$  classifies the integers 3, 4 and 5 as positive and all others as negative.

Instance	Class
1	Negative
2	Positive
3	Positive
4	Positive
5	Negative

# A) [15 marks]

Apply the Halving Algorithm to the five examples in the order in which they appear in the table above. Show each class prediction and whether or not it is a mistake, plus the initial G and S sets and those at the end of each iteration.

# B) [5 marks]

What is the worst-case mistake bound for the Halving Algorithm given the hypothesis space described above? Give an informal derivation of your bound.

# Question 4 [20 marks]

Evaluation of Learning

#### A) [3 marks]

The AUC (area under the ROC curve) measure originated in signal detection theory. For the evaluation of classifier learning on a two-class prediction problem, explain the *probabilistic* interpretation of this measure.

#### B) [3 marks]

You have implemented a new two-class classifier learning algorithm that outputs a "score" to indicate how strongly it believes an input instance to be in the positive class. Explain how to you would use a *margin*-based approach to penalise incorrect classifications.

#### (C) [14 marks]

Suppose the following decision tree has been learned on a training set of 10 positive and 10 negative examples for a "play sport" task.

```
Outlook = sunny:
    Temperature = warm: [ play (5); don't play (2) ]
    Temperature = cold: [ play (4); don't play (3) ]
Outlook = rainy: [ play (1); don't play (5) ]
```

The three leaves of the tree each show the number of positive (play) and negative (don't play) examples in each leaf. Using a scoring function based on the ratio of positive to negative examples in each leaf node, generate the *ranking* of the training set produced by this scoring function. Then compute the *ranking error* for the tree on the training data.

# Question 5 [20 Marks]

Computational Learning Theory

#### A) [8 marks]

An instance space X is defined using m Boolean attributes. Let the hypothesis space H be the set of decision trees defined on X (you can assume two classes). What is the largest set of instances in this setting which is shattered by H? [Show your reasoning.]

# B) [10 marks]

Suppose we have a consistent learner with a hypothesis space restricted to conjunctions of exactly 8 attributes, each with values {true, false, don't care}. What is the size of this learner's hypothesis space? Give the formula for the number of examples sufficient to learn with probability at least 95% an approximation of any hypothesis in this space with error of at most 10%. [Note: you are *not* required to compute the solution.]

#### (C) [2 marks]

Informally, which of the following are consequences of the No Free Lunch theorem:

- a) averaged over all possible training sets, the variance of a learning algorithm dominates its bias
- b) averaged over all possible training sets, no learning algorithm has a better off-training set error than any other
- c) averaged over all possible target concepts, the bias of a learning algorithm dominates its variance
- d) averaged over all possible target concepts, no learning algorithm has a better offtraining set error than any other
- e) averaged over all possible target concepts and training sets, no learning algorithm is independent of the choice of representation in terms of its classification error

# Question 6 [20 marks]

Ensemble Learning

# A) [8 marks]

As model complexity increases from low to high, what effect does this have on:

- 1) Bias?
- 2) Variance?
- 3) Predictive accuracy on training data?
- 4) Predictive accuracy on test data?

#### B) [3 marks]

Is decision tree learning relatively stable? Describe decision tree learning in terms of bias and variance in no more than two sentences.

# (C) [3 marks]

Is nearest neighbour relatively stable? Describe nearest neighbour in terms of bias and variance in no more than two sentences.

# D) [3 marks]

Bagging reduces bias. True or false? Give a one sentence explanation of your answer.

#### E) [3 marks]

Bagging reduces variance. True or false? Give a one sentence explanation of your answer.

# Question 7 [20 marks]

Bayesian Learning

# A) [4 marks]

Explain the difference between the maximum a posteriori hypothesis  $H_{\mathrm{MAP}}$  and the maximum likelihood hypothesis  $H_{\mathrm{ML}}$ .

#### B) [2 marks]

Consider a two-class learning problem to "Play tennis", with two Boolean attributes, "Cloudy" and "Windy". Draw the Bayesian network corresponding to a Naive Bayes classifier for this problem.

# (C) [10 marks]

Given the following examples, calculate *all* the probabilities required for your Naive Bayes classifier to be able to decide whether to play or not:

Instance No.	Cloudy	Windy	Play tennis
1	0	0	no
2	0	1	no
3	1	1	no
4	0	0	no
5	0	1	yes
6	1	0	yes

#### D) [4 marks]

To which class would your Naive Bayes classifier assign each of the following instances?

Instance No.	Cloudy	Windy	Play tennis
7	0	0	?
8	0	1	?

Name of Candidate:	
Student number:	
Signature:	

# COMP9417 Machine Learning and Data Mining Final Examination: SAMPLE QUESTIONS

HERE ARE SEVEN QUESTIONS WHICH ARE REPRESENTATIVE OF THE TYPE THAT WILL BE IN THE FINAL EXAM. EACH QUESTION IS OF EQUAL VALUE, AND SHOULD NOT TAKE LONGER THAN 30 MINUTES TO COMPLETE. IN THE ACTUAL EXAM THERE WILL BE SOME DEGREE OF CHOICE AS TO WHICH QUESTIONS YOU CAN ANSWER. CANDIDATES MAY BRING AUTHORISED CALCULATORS TO THE EXAMINATION, BUT NO OTHER MATERIALS WILL BE PERMITTED.

# Question 1 [20 marks]

Association Rule Learning & and ILP

#### A) [7 marks]

An association rule has the form  $A \to C$  where A is the antecedent and C is the consequent. Suppose you have a database of one million transactions.

- 1) If an association rule has 90% support, how many transactions contain all the items in A?
- 2) For the same rule, how many transactions contain all the items in C?
- 3) For the same rule, how many transactions contain all the items in both A and C?
- 4) If another rule has 40% support and 100% confidence, how many transactions contain all the items in A?
- 5) If yet another rule has 40% support and 50% confidence, how many transactions contain all the items in A?

#### B) [**3 marks**]

You are mining a data warehouse. In three sentences or less propose a method to derive all candidate item sets of size k + 1 from the k-item sets with at least minimum support.

# (C) **[4 marks]**

Consider the following two clauses:

$$C = Q(A, x, B) \vee S(y, B)$$
 and  $C_1 = S(w, B) \vee \neg R(z)$ 

Using inverse resolution, provide at least one solution for  $C_2$ . [Show all substitutions].

#### D [6 marks]

Construct the **Relative Least General Generalisation** (**RLGG**) of two observations: likes(alan,sushi) and likes(alan,curry), given the background predicates food(sushi) and food(curry). Now suppose you are given two more observations: likes(bettina,sushi) and likes(bettina,curry). Will the RLGG of the four observations, given the same background predicates, change? If you think the answer is yes, give the new RLGG, otherwise give an argument why it will not have changed. [Show all working].

# Question 2 [20 marks]

Comparing Lazy and Eager Learning

The following truth table gives an "m-of-n function" for three Boolean variables, where "1" denotes true and "0" denotes false. In this case the target function is: "exactly two out of three variables are true".

X	Y	Z	Class
0	0	0	false
0	0	1	false
0	1	0	false
0	1	1	true
1	0	0	false
1	0	1	true
1	1	0	true
1	1	1	false

# A) [4 marks]

Construct a decision tree which is complete and correct for the examples in the table. [Hint: draw a diagram.]

# B) [4 marks]

Construct a set of **ordered** classification rules which is complete and correct for the examples in the table. [Hint: use an *if-then-else* representation.]

# C) [10 marks]

Suppose we define a simple measure of distance between two equal length strings of Boolean values, as follows. The distance between two such strings  $B_1$  and  $B_2$  is:

$$\operatorname{distance}(B_1,B_2) = |(\sum B_1) - (\sum B_2)|$$

where  $\sum B_i$  is simply the number of variables with value 1 in string  $B_i$ . For example:

$$distance(\langle 0,0,0\rangle,\langle 1,1,1\rangle)=|0-3|=3$$

and

distance(
$$(1, 0, 0), (0, 1, 0)$$
) =  $|1 - 1| = 0$ 

What is the LOOCV ("Leave—one—out cross-validation") error of 2—Nearest Neighbour using our distance function on the examples in the table? [Show your working.]

# D) [2 marks]

Compare your three models. Which do you conclude provides a better representation for this particular problem? Give your reasoning (one sentence).

# Question 3 [20 Marks]

Mistake Bounds

Consider the following learning problem on an instance space which has only one feature, i.e., each instance is a *single integer*. Suppose instances are always in the range [1, 5]. The hypothesis space is one in which each hypothesis is an interval over the integers. More precisely, each hypothesis h in the hypothesis space H is an interval of the form  $a \le x \le b$ , where a and b are integer constants and x refers to the instance. For example, the hypothesis  $3 \le x \le 5$  classifies the integers 3, 4 and 5 as positive and all others as negative.

Instance	Class
1	Negative
2	Positive
3	Positive
4	Positive
5	Negative

# A) [15 marks]

Apply the Halving Algorithm to the five examples in the order in which they appear in the table above. Show each class prediction and whether or not it is a mistake, plus the initial G and S sets and those at the end of each iteration.

# B) **[5 marks]**

What is the worst-case mistake bound for the Halving Algorithm given the hypothesis space described above? Give an informal derivation of your bound.

# Question 4 [20 marks]

Evaluation of Learning

#### A) [3 marks]

You have implemented a new two-class classifier learning algorithm that outputs a "score" to indicate how strongly it believes an input instance to be in the positive class. Explain how you could use a *margin*-based approach to penalise incorrect classifications.

#### B) [3 marks]

The AUC (area under the ROC curve) measure originated in signal detection theory. For the evaluation of classifier learning on a two-class prediction problem, can you think of a *probabilistic* interpretation of this measure?

# (C) [14 marks]

Suppose the following decision tree has been learned on a training set of 10 positive and 10 negative examples for a "play sport" task.

```
Outlook = sunny:
    Temperature = warm: [ play (5); don't play (2) ]
    Temperature = cold: [ play (4); don't play (3) ]
Outlook = rainy: [ play (1); don't play (5) ]
```

The three leaves of the tree each show the number of positive (play) and negative (don't play) examples in each leaf. Using a scoring function based on the ratio of positive to negative examples in each leaf node, generate the *ranking* of the training set produced by this scoring function. Then compute the *ranking error* for the tree on the training data.

# Question 5 [20 Marks]

Computational Learning Theory

#### A) [8 marks]

An instance space X is defined using m Boolean attributes. Let the hypothesis space H be the set of decision trees defined on X (you can assume two classes). What is the largest set of instances in this setting which is shattered by H? [Show your reasoning.]

# B) [10 marks]

Suppose we have a consistent learner with a hypothesis space restricted to conjunctions of exactly 8 attributes, each with values {true, false, don't care}. What is the size of this learner's hypothesis space? Give the formula for the number of examples sufficient to learn with probability at least 95% an approximation of any hypothesis in this space with error of at most 10%. [Note: you are *not* required to compute the solution.]

#### (C) [2 marks]

Informally, which of the following are consequences of the No Free Lunch theorem:

- a) averaged over all possible training sets, the variance of a learning algorithm dominates its bias
- b) averaged over all possible training sets, no learning algorithm has a better off-training set error than any other
- c) averaged over all possible target concepts, the bias of a learning algorithm dominates its variance
- d) averaged over all possible target concepts, no learning algorithm has a better offtraining set error than any other
- e) averaged over all possible target concepts and training sets, no learning algorithm is independent of the choice of representation in terms of its classification error

# Question 6 [20 marks]

Ensemble Learning

# A) [8 marks]

As model complexity increases from low to high, what effect does this have on:

- 1) Bias?
- 2) Variance?
- 3) Predictive accuracy on training data?
- 4) Predictive accuracy on test data?

#### B) [3 marks]

Is decision tree learning relatively stable? Describe decision tree learning in terms of bias and variance in no more than two sentences.

# (C) [3 marks]

Is nearest neighbour relatively stable? Describe nearest neighbour in terms of bias and variance in no more than two sentences.

#### D) [3 marks]

Bagging reduces bias. True or false? Give a one sentence explanation of your answer.

# E) [3 marks]

Boosting reduces variance. True or false? Give a one sentence explanation of your answer.

# Question 7 [20 marks]

Bayesian Learning

# A) [4 marks]

Explain the difference between the maximum a posteriori hypothesis  $H_{\mathrm{MAP}}$  and the maximum likelihood hypothesis  $H_{\mathrm{ML}}$ .

#### B) [2 marks]

Consider a two-class learning problem to "Play tennis", with two Boolean attributes, "Cloudy" and "Windy". Draw the Bayesian network corresponding to a Naive Bayes classifier for this problem.

# (C) [10 marks]

Given the following examples, calculate *all* the probabilities required for your Naive Bayes classifier to be able to decide whether to play or not:

Instance No.	Cloudy	Windy	Play tennis
1	0	0	no
2	0	1	no
3	1	1	no
4	0	0	no
5	0	1	yes
6	1	0	yes

#### D) [4 marks]

To which class would your Naive Bayes classifier assign each of the following instances?

Instance No.	Cloudy	Windy	Play tennis
7	0	0	?
8	0	1	?

Name of Candidate:	
Student number:	
Signature:	

# COMP9417 Machine Learning and Data Mining

Final Examination: SAMPLE QUESTIONS

Here are seven questions which are *somewhat* representative of the type that will be in the final exam. Each question is of equal value, and should not take longer than 30 minutes to complete. In the actual exam there will be some degree of choice as to which questions you can answer. Candidates may bring authorised calculators to the examination, but no other materials will be permitted.

# Question 1 [20 marks]

Comparing Lazy and Eager Learning

The following truth table gives an "m-of-n function" for three Boolean variables, where "1" denotes true and "0" denotes false. In this case the target function is: "exactly two out of three variables are true".

X	Y	Z	Class
0	0	0	false
0	0	1	false
0	1	0	false
0	1	1	true
1	0	0	false
1	0	1	true
1	1	0	true
1	1	1	false

# A) [4 marks]

Construct a decision tree which is complete and correct for the examples in the table. [Hint: draw a diagram.]

# B) [4 marks]

Construct a set of **ordered** classification rules which is complete and correct for the examples in the table. [Hint: use an *if-then-else* representation.]

# C) [10 marks]

Suppose we define a simple measure of distance between two equal length strings of Boolean values, as follows. The distance between two such strings  $B_1$  and  $B_2$  is:

$$\operatorname{distance}(B_1,B_2) = |(\sum B_1) - (\sum B_2)|$$

where  $\sum B_i$  is simply the number of variables with value 1 in string  $B_i$ . For example:

$$\operatorname{distance}(\langle 0,0,0\rangle,\langle 1,1,1\rangle)=|0-3|=3$$

and

distance(
$$(1, 0, 0), (0, 1, 0)$$
) =  $|1 - 1| = 0$ 

What is the LOOCV ("Leave-one-out cross-validation") error of 2-Nearest Neighbour using our distance function on the examples in the table? [Show your working.]

# D) [2 marks]

Compare your three models. Which do you conclude provides a better representation for this particular problem? Give your reasoning (one sentence).

# Question 2 [20 marks]

Learning in Logic

#### A) [6 marks]

Consider the following two clauses:

$$C = Q(A, x, B) \vee S(y, B)$$
 and  $C_1 = S(w, B) \vee \neg R(z)$ 

Using inverse resolution, provide at least one solution for  $C_2$ . [Show all substitutions].

#### B [8 marks]

Construct the *Relative Least General Generalisation (RLGG)* of two observations: likes(alan,sushi) and likes(alan,curry), given the background predicates food(sushi) and food(curry). Now suppose you are given two more observations: likes(bettina,sushi) and likes(bettina,curry). Will the RLGG of the four observations, given the same background predicates, change? If you think the answer is yes, give the new RLGG, otherwise give an argument why it will not have changed. [Show all working].

# (C) **[6 marks]**

Explain how the *generality* order on hypotheses can be expressed for hypotheses that are atoms in first-order logic. Suggest refinement operator for such atoms that could be used to search the hypothesis space.

# Question 3 [20 marks]

Bayesian Learning

# A) [4 marks]

Explain the difference between the maximum a posteriori hypothesis  $H_{\mathrm{MAP}}$  and the maximum likelihood hypothesis  $H_{\mathrm{ML}}$ .

# B) [2 marks]

Consider a two-class learning problem to "Play tennis", with two Boolean attributes, "Cloudy" and "Windy". Draw the Bayesian network corresponding to a Naive Bayes classifier for this problem.

# (C) [10 marks]

Given the following examples, calculate *all* the probabilities required for your Naive Bayes classifier to be able to decide whether to play or not:

Instance No.	Cloudy	Windy	Play tennis
1	0	0	no
2	0	1	no
3	1	1	no
4	0	0	no
5	0	1	yes
6	1	0	yes

# D) [4 marks]

To which class would your Naive Bayes classifier assign each of the following instances?

Instance No.	Cloudy	Windy	Play tennis
7	0	0	?
8	0	1	?

# Question 4 [20 marks]

Ensemble Learning

# A) [8 marks]

As model complexity increases from low to high, what effect does this have on:

- 1) Bias?
- 2) Variance?
- 3) Predictive accuracy on training data?
- 4) Predictive accuracy on test data?

#### B) [3 marks]

Is decision tree learning relatively stable? Describe decision tree learning in terms of bias and variance in no more than two sentences.

# (C) [3 marks]

Is nearest neighbour relatively stable? Describe nearest neighbour in terms of bias and variance in no more than two sentences.

#### D) [3 marks]

Bagging reduces bias. True or false? Give a one sentence explanation of your answer.

#### E) [3 marks]

Boosting reduces variance. True or false? Give a one sentence explanation of your answer.

# Question 5 [20 marks]

Evaluation of Learning

#### A) [6 marks]

The AUC (area under the ROC curve) measure originated in signal detection theory. For the evaluation of classifier learning on a two-class prediction problem, can you think of a *probabilistic* interpretation of this measure? In this setting, under what conditions does this measure achieve its maximum and minimum values?

# B) [8 marks]

Suppose we specify the outcome of learning a two-class classifier with the following contingency table:

	Predicted Class	
Actual Class	Yes	No
Yes	TP	FN
No	FP	TN

Two widely-used measures are true positive rate or sensitivity which is  $TPR = \frac{TP}{TP+FN}$ , and true negative rate or specificity which is  $TNR = \frac{TN}{TN+FP}$ . Explain how accuracy can be calculated as a weighted average of TPR and TNR.

# (C) **[6 marks]**

Once again, for a two-class classification problem, suppose you have the following setting:

- a data set D has a uniform class distribution, i.e., the class ratio is 1;
- on a coverage plot, two classifiers are evaluated on D and their classification performance is represented by two points  $C_1$  and  $C_2$  on the coverage plot;
- you observe that  $C_1$  and  $C_2$  can be connected on the coverage plot by a straight line of slope 1.

Which of the classifiers,  $C_1$  or  $C_2$ , has greater accuracy? Explain your answer.

# Question 6 [20 Marks]

Computational Learning Theory

#### A) [8 marks]

An instance space X is defined using m Boolean attributes. Let the hypothesis space H be the set of decision trees defined on X (you can assume two classes). What is the largest set of instances in this setting which is shattered by H? [Show your reasoning.]

# B) [10 marks]

Suppose we have a consistent learner with a hypothesis space restricted to conjunctions of exactly 8 attributes, each with values {true, false, don't care}. What is the size of this learner's hypothesis space? Give the formula for the number of examples sufficient to learn with probability at least 95% an approximation of any hypothesis in this space with error of at most 10%. [Note: you are *not* required to compute the solution.]

#### (C) [2 marks]

Informally, which of the following are consequences of the No Free Lunch theorem:

- a) averaged over all possible training sets, the variance of a learning algorithm dominates its bias
- b) averaged over all possible training sets, no learning algorithm has a better off-training set error than any other
- c) averaged over all possible target concepts, the bias of a learning algorithm dominates its variance
- d) averaged over all possible target concepts, no learning algorithm has a better offtraining set error than any other
- e) averaged over all possible target concepts and training sets, no learning algorithm is independent of the choice of representation in terms of its classification error

# Question 7 [20 Marks]

Mistake Bounds

Consider the following learning problem on an instance space which has only one feature, i.e., each instance is a *single integer*. Suppose instances are always in the range [1, 5]. The hypothesis space is one in which each hypothesis is an interval over the integers. More precisely, each hypothesis h in the hypothesis space H is an interval of the form  $a \le x \le b$ , where a and b are integer constants and x refers to the instance. For example, the hypothesis  $3 \le x \le 5$  classifies the integers 3, 4 and 5 as positive and all others as negative.

Instance	Class
1	Negative
2	Positive
3	Positive
4	Positive
5	Negative

# A) [15 marks]

Apply the Halving Algorithm to the five examples in the order in which they appear in the table above. Show each class prediction and whether or not it is a mistake, plus the initial G and S sets and those at the end of each iteration.

# B) **[5 marks]**

What is the worst-case mistake bound for the Halving Algorithm given the hypothesis space described above? Give an informal derivation of your bound.

Final Examination: SAMPLE QUESTIONS

Here are seven questions which are *somewhat* representative of the type that will be in the final exam. Each question is of equal value, and should not take longer than 30 minutes to complete. In the actual exam there will be some degree of choice as to which questions you can answer. Candidates may bring authorised calculators to the examination, but no other materials will be permitted.

# Question 1 [20 marks]

Comparing Lazy and Eager Learning

The following truth table gives an "m-of-n function" for three Boolean variables, where "1" denotes true and "0" denotes false. In this case the target function is: "exactly two out of three variables are true".

X	Y	Z	Class
0	0	0	false
0	0	1	false
0	1	0	false
0	1	1	true
1	0	0	false
1	0	1	true
1	1	0	true
1	1	1	false

# A) [4 marks]

Construct a decision tree which is complete and correct for the examples in the table. [Hint: draw a diagram.]

# B) [4 marks]

Construct a set of **ordered** classification rules which is complete and correct for the examples in the table. [Hint: use an *if-then-else* representation.]

# C) [10 marks]

Suppose we define a simple measure of distance between two equal length strings of Boolean values, as follows. The distance between two such strings  $B_1$  and  $B_2$  is:

$$\operatorname{distance}(B_1,B_2) = |(\sum B_1) - (\sum B_2)|$$

where  $\sum B_i$  is simply the number of variables with value 1 in string  $B_i$ . For example:

$$\operatorname{distance}(\langle 0,0,0\rangle,\langle 1,1,1\rangle)=|0-3|=3$$

and

distance(
$$(1, 0, 0), (0, 1, 0)$$
) =  $|1 - 1| = 0$ 

What is the LOOCV ("Leave—one—out cross-validation") error of 2—Nearest Neighbour using our distance function on the examples in the table? [Show your working.]

# D) [2 marks]

Compare your three models. Which do you conclude provides a better representation for this particular problem? Give your reasoning (one sentence).

# Question 2 [20 marks]

Bayesian Learning

# A) [4 marks]

Explain the difference between the maximum a posteriori hypothesis  $H_{\rm MAP}$  and the maximum likelihood hypothesis  $H_{\rm ML}$ .

# B) [2 marks]

Consider a two-class learning problem to "Play tennis", with two Boolean attributes, "Cloudy" and "Windy". Draw the Bayesian network corresponding to a Naive Bayes classifier for this problem.

# (C) [10 marks]

Given the following examples, calculate *all* the probabilities required for your Naive Bayes classifier to be able to decide whether to play or not:

Instance No.	Cloudy	Windy	Play tennis
1	0	0	no
2	0	1	no
3	1	1	no
4	0	0	no
5	0	1	yes
6	1	0	yes

# D) [4 marks]

To which class would your Naive Bayes classifier assign each of the following instances?

Instance No.	Cloudy	Windy	Play tennis
7	0	0	?
8	0	1	?

# Question 3 [20 marks]

Neural Networks

#### A) [4 marks]

A *linear unit* from neural networks is a linear model for numeric prediction that is fitted by gradient descent. Explain the differences between the *batch* and *incremental* (or *stochastic*) versions of gradient descent.

# B) [4 marks]

Stochastic gradient descent would be expected to deal better with local minima during learning than batch gradient descent – true or false? Explain your reasoning.

# A) [12 marks]

Suppose a single unit has output o the form:

$$o = w_0 + w_1 x_1 + w_1 x_1^2 + w_2 x_2 + w_2 x_2^2 + \dots + w_n x_n + w_n x_n^2$$

The problem is to learn a set of weights  $w_i$  that minimize squared error. Derive a batch gradient descent training rule for this unit.

# Question 4 [20 marks]

Ensemble Learning

# A) [8 marks]

As model complexity increases from low to high, what effect does this have on:

- 1) Bias?
- 2) Variance?
- 3) Predictive accuracy on training data?
- 4) Predictive accuracy on test data?

#### B) [3 marks]

Is decision tree learning relatively stable? Describe decision tree learning in terms of bias and variance in no more than two sentences.

# (C) [3 marks]

Is nearest neighbour relatively stable? Describe nearest neighbour in terms of bias and variance in no more than two sentences.

#### D) [3 marks]

Bagging reduces bias. True or false? Give a one sentence explanation of your answer.

#### E) [3 marks]

Boosting reduces variance. True or false? Give a one sentence explanation of your answer.

# Question 5 [20 Marks]

Computational Learning Theory

#### A) [8 marks]

An instance space X is defined using m Boolean attributes. Let the hypothesis space H be the set of decision trees defined on X (you can assume two classes). What is the largest set of instances in this setting which is shattered by H? [Show your reasoning.]

# B) [10 marks]

Suppose we have a consistent learner with a hypothesis space restricted to conjunctions of exactly 8 attributes, each with values {true, false, don't care}. What is the size of this learner's hypothesis space? Give the formula for the number of examples sufficient to learn with probability at least 95% an approximation of any hypothesis in this space with error of at most 10%. [Note: you are *not* required to compute the solution.]

#### (C) [2 marks]

Informally, which of the following are consequences of the No Free Lunch theorem:

- a) averaged over all possible training sets, the variance of a learning algorithm dominates its bias
- b) averaged over all possible training sets, no learning algorithm has a better off-training set error than any other
- c) averaged over all possible target concepts, the bias of a learning algorithm dominates its variance
- d) averaged over all possible target concepts, no learning algorithm has a better offtraining set error than any other
- e) averaged over all possible target concepts and training sets, no learning algorithm is independent of the choice of representation in terms of its classification error

# Question 6 [20 Marks]

Mistake Bounds

Consider the following learning problem on an instance space which has only one feature, i.e., each instance is a *single integer*. Suppose instances are always in the range [1, 5]. The hypothesis space is one in which each hypothesis is an interval over the integers. More precisely, each hypothesis h in the hypothesis space H is an interval of the form  $a \le x \le b$ , where a and b are integer constants and x refers to the instance. For example, the hypothesis  $3 \le x \le 5$  classifies the integers 3, 4 and 5 as positive and all others as negative.

Instance	Class
1	Negative
2	Positive
3	Positive
4	Positive
5	Negative

# A) [15 marks]

Apply the Halving Algorithm to the five examples in the order in which they appear in the table above. Show each class prediction and whether or not it is a mistake, plus the initial G and S sets and those at the end of each iteration.

# B) **[5 marks]**

What is the worst-case mistake bound for the Halving Algorithm given the hypothesis space described above? Give an informal derivation of your bound.
